Introduction

• Molecular wave function in the adiabatic representation $\Psi(r, R, t) = \sum_{j} \chi_{n,j}(R, t) \phi_{e,j}(r; R)$ $H_e \phi_{e,j} = E_j(R) \phi_{e,j}(r; R)$

Modeling the system

N-dimensional LVC Hamiltonian for nuclear DOF $H_{ND} = \sum_{i}^{N} (p_j^2 + \omega_j^2 q_j^2) \mathbf{1}_2 + \begin{bmatrix} -\kappa_j q_j & c_j q_j \\ c_j q_j & \kappa_j q_j \end{bmatrix} + \begin{bmatrix} -\delta & 0 \\ 0 & \delta \end{bmatrix}$

GP effects for transfer

Expand the nuclear wave function: y - y + y

- If electronic surfaces, $E_j(R)$, intersect conically, geometric phase (GP) makes the electronic functions double-valued.
- To compensate for that:¹ $\phi_{e,j}(r;R)e^{-i\theta(R)}$ $\chi_{n,j}(R,t)e^{i\theta(R)}$

Questions:
When is GP important?
What is the impact of extra nuclear degrees of freedom (DOF)?

Motivation:

To develop a qualitative picture of GP effects in excited state dynamics of large system.

The short-time dynamics can be examined by an effective 2D system². Extra DOF modify the 2D parameters.

Adiabatic representation (no GP if single-value real wave functions are used):

 $H_{adi} = -\frac{1}{2}\nabla^2 \mathbf{1}_2 + \begin{bmatrix} W_- & 0\\ 0 & W_+ \end{bmatrix} + \begin{bmatrix} \tau_{11} & \tau_{12}\\ -\tau_{12} & \tau_{22} \end{bmatrix}$ $W_{\pm} = \frac{1}{2}(V_{11} + V_{22}) \pm \frac{1}{2}\sqrt{(V_{11} - V_{22})^2 + 4V_{12}^2}$ $\tau_{ij} = -\langle \phi_i | \nabla \phi_j \rangle \nabla - \frac{1}{2} \langle \phi_i | \nabla^2 \phi_j \rangle$

It is the angular-momentum free (m=0) component of a wave packet³. Good approximation to $\chi_{nontran}$ when $\gamma \sim 1$.

 \geq

How geometry affects the nontransferable weight (m=0) and the importance of GP

Population plots: solid - with GP, dashed - without GP.

Constant coupling (Δ_{12}) : a shift of CI along y-axis

Orthogonality of coupling: breaking down of the wave packet's symmetry

Difference in potential minima (Δ): a change in kinetic energy
